ABSTRACT

This article aims to provide a concise, structured approach to the child with chest pain. Chest pain is a common presenting symptom in children but, unlike in adults, the cause is rarely cardiac. We review the main causes of chest pain in children and discuss the important features that may alert those assessing paediatric chest pain to serious underlying pathology. In the vast majority of cases, reassurance is all that is required and a thorough initial consultation can exclude rare, serious disease and provide vital reassurance to children and families.

INTRODUCTION

Chest pain is a relatively common presenting symptom in children that causes a great deal of anxiety in patients, parents and healthcare professionals. It affects approximately equal numbers of children under and over 12, with no particular gender bias.¹ The anxiety surrounding chest pain most likely arises from the association between chest pain and cardiac ischaemia in adults and media coverage of sudden cardiac deaths; however, underlying cardiac pathology is rare in children with chest pain and parents/patients can usually be reassured that there is not a serious underlying cause.² The two largest studies to date looked at a total of 8136 children presenting to emergency departments with chest pain and found that only 0.6–1% of these had a cardiac cause for their pain.^{3 4} Despite this, a study of 100 adolescents with chest pain showed a significant impact on quality of life with over 40% absent from school with their chest pain and 44% believing their chest pain was a result of a 'heart attack'.⁵ This study highlights the degree of unwarranted anxiety that chest pain can cause. A chest pain consultation should, therefore, focus on acknowledging the patient/

parental fears, exclusion of rare, serious underlying pathology and appropriate reassurance.

Table 1 summarises the major causes of chest pain in approximate order of frequency. Although the majority of patients do not have a serious underlying diagnosis, it is clearly important to quickly assess those that may be at increased risk.

Previous studies have shown that a thorough history and physical examination are sufficient, in the vast majority of cases, to exclude a serious cause for the pain.^{4 7 8} Targeted diagnostic testing can then be performed to address concerns identified. The potential causes of chest pain have been reviewed more fully by Ives *et al*⁹ but here we present an approach to assessment.

HISTORY

A detailed history is vital when assessing a child with chest pain as a thorough enquiry into the nature of the pain and associated features may be all that is needed to make a definitive diagnosis.^{4 8 10}

Age is a consideration when assessing these patients; adolescents are more likely to have musculoskeletal or psychogenic causes for chest pain, while young children may interpret a wide range of symptoms or chest sensations as pain. Box 1 describes some of the 'red flag' features that should alert to a potential cardiac cause. The differing characteristics of the chest pain in each of the main categories are as follows:

Musculoskeletal

- ▶ Usually well localised and can often be reproduced with palpation or gentle sternal pressure.
- ▶ Worse with movement, coughing and inspiration.
- ▶ See table 2 for more details.

Table 1 Major causes of chest pain in children with approximate percentage of all chest pain presentations from published literature^{1 3 4 6}

Group	Pathogenesis	Approx. percentage
Musculoskeletal	Costochondritis Tietze's syndrome Precordial catch	24–56
Respiratory	Cough Bronchospasm Pleuritic processes (pneumonia/ pneumothorax/pulmonary embolus)	7–20
Idiopathic		12–52
Psychogenic	Anxiety Hyperventilation/disordered breathing	1–9
Gastrointestinal	Acid reflux Oesophagitis Gastric ulceration	3–6
Miscellaneous	Herpes Zoster Sickle cell crisis Tumours (chest wall/mediastinal)	4–11
Cardiac	Pericarditis Arrhythmia Myocardial ischaemia (eg, aortic stenosis, hypertrophic obstructive cardiomyopathy, coronary artery disease) Mitral valve prolapse Myocarditis	0.6–1

Respiratory

- ▶ Pain from asthma often described as 'tightness', associated with wheeze, shortness of breath and dry cough.
- ▶ Pleuritic pain is usually sharp and localised, exacerbated by inspiration and coughing.
- ▶ Pain from pneumothorax will be ipsilateral and is often felt in the upper anterior part of the chest.

Psychogenic

- ▶ Often recurrent with particular stressors.
- ▶ History of anxiety (particularly panic disorder) and/or stressful life events.
- ▶ May be associated with hyperventilation.

Gastrointestinal

- ▶ Often retrosternal or epigastric, but may also be central.
- ▶ Typically burning or sharp in nature.
- ▶ May be exacerbated with eating or posture.
- ▶ Can be associated with heartburn, water brash (production of excess saliva in response to acid in the oesophagus) or dysphagia.

Cardiac

- ▶ Centrally located and may radiate to the left arm/jaw region.
- ▶ Typically described as crushing pain or heaviness, like 'an elephant sat on my chest'.
- ▶ Associated autonomic symptoms such as sweatiness, nausea or pallor.
- ▶ Chest pain on exertion is particularly significant, especially if the pain is of a typical cardiac nature.
- ▶ Associated presyncope, syncope and palpitations.

Box 1 Potential red flags that increase the likelihood of a cardiac cause for chest pain

- ▶ Personal past or current history of acquired or congenital cardiac disease*
- ▶ Exertional syncope
- ▶ Exertional cardiac-type chest pain
- ▶ Hypercoagulable or hypercholesterolaemic state
- ▶ Family history of:
sudden death under 35 years of age
young onset ischaemic heart disease
inherited arrhythmias such as long QT syndrome or Brugada
- ▶ Implantable cardioverter defibrillators in situ
- ▶ Connective tissue disorders
- ▶ History of cocaine/amphetamine use

*Although a history of congenital heart disease is not necessarily a risk factor for chest pain, in the absence of other obvious diagnoses, referral back to the paediatric cardiologist for reassurance may be appropriate.

It is also important to include the following key areas of enquiry:

- ▶ Is there any history of trauma or preceding new or intense physical activity?
- ▶ How long has the pain been present?
- ▶ Is the pain associated with any particular activities such as eating or exercise?
- ▶ How often does the pain occur and how long does each episode last?
- ▶ Are there any exacerbating factors, for example, exercise, certain positions, movement and coughing?
- ▶ Are there any alleviating factors such as positional changes, rest, analgesics and antacids?
- ▶ Any dyspnoea, cough, wheeze or other respiratory symptoms?
- ▶ Have there been any associated constitutional symptoms such as fever, anorexia and weight loss?
- ▶ Are there any potentially cardiac-related symptoms or risk factors, including palpitations, syncope, family history of sudden death, implantable cardioverter defibrillators (ICD), arrhythmias, previous Kawasaki disease or congenital heart disease?
- ▶ Any vomiting, heartburn, dysphagia, water brash or other gastrointestinal symptoms?
- ▶ Are there any underlying medical conditions that may be associated with chest pain such as asthma, Kawasaki disease and sickle cell disease?
- ▶ Is there any history of possible substance abuse?
- ▶ Any recent stressors at home or school? Any problems with anxiety?

Table 2 summarises the clinical features of the principal causes of chest pain in children and provides concise details of further management and prognosis.

Table 2 Major features of the principal causes of chest pain in children and relevant investigation/treatment

Signs and symptoms	Diagnosis	Prognosis/management
<i>Musculoskeletal</i>		
<ul style="list-style-type: none"> • Sharp, anterior chest wall pain over multiple costochondral/costosternal junctions • Usually first to fifth ribs • Pain on palpation. No swelling 	Costochondritis	Pain resolves with NSAIDs and rest. May last many months, very rarely needs intra-articular steroids ⁷
<ul style="list-style-type: none"> • Sharp localised pain at one costochondral junction • Tender, swollen (1–4 cm mass), not hot • Most frequently 2nd or 3rd costochondral junction 	Tietze's syndrome	Pain resolves with NSAIDs and rest. Lasts up to 2 months ⁷
<ul style="list-style-type: none"> • Aching pain after new or intense exercise • Can appear up to 2 days later • Pain reproduced by palpation and range of movement testing 	Muscular strain	Pain resolves with NSAIDs and rest ¹¹
<ul style="list-style-type: none"> • Sudden sharp chest pain • Occurs mainly at rest • Usually left sided • Lasts a few seconds to 3 min • Exacerbated by deep inspiration • No signs/associated symptoms 	Precordial catch	Reassurance ¹²
<ul style="list-style-type: none"> • Pain under 8th–10th ribs anteriorly when medial fibrous attachments are inadequate or ruptured • Exacerbated by sudden upward movement (eg, horse riding) and flexing of trunk • Sometimes popping sensation at onset of pain • Rare—more common in athletes • Hooking manoeuvre reproduces 	Slipping rib syndrome	Resolves with rest and NSAIDs ¹¹
<i>Gastrointestinal/respiratory</i>		
<ul style="list-style-type: none"> • Wheeze ± dyspnoea • Exercise-induced asthma can often cause chest pain with exercise even in the absence of wheeze 	Asthma/wheeze	Spirometry Consider exercise test spirometry Trial of bronchodilator ^{2 13}
<ul style="list-style-type: none"> • Retrosternal burning • Water brash/ascending pain • Pain associated with posture, eating • Epigastric tenderness • Associated dysphagia suggests oesophageal origin 	Gastro-oesophageal reflux, oesophagitis, gastritis	Trial of reflux treatment Consider pH/impedance study ¹⁴
<ul style="list-style-type: none"> • Sharp, sudden onset chest pain with significant dyspnoea • Pain diffuse on the affected side with radiation to ipsilateral shoulder • Risk factors include a tall, thin body habitus, asthma, cystic fibrosis, inhalation of cocaine or marijuana 	Pneumothorax	CXR Conservative/interventional management
<i>Non-organic</i>		
<ul style="list-style-type: none"> • Breathlessness without exertion, inability to obtain a satisfying breath, frequent yawning or sighing • Rapid, shallow or deep breathing during acute episode • Lightheadedness or dizziness 	Disordered breathing/hyperventilation	Physiotherapy ¹⁵
<ul style="list-style-type: none"> • Pain often fleeting or vague or localised over precordium +/- or left arm • History of stressful events • Other recurrent somatic complaints, including headache or abdominal or extremity pain 	Psychogenic	Reassurance ± psychological input ¹⁶
<i>Cardiac</i>		
<ul style="list-style-type: none"> • Sharp (anterior/precordial) • Exacerbated by leaning forward • ± systemic upset 	Pericarditis	ECG to assess for widespread ST elevation Inflammatory markers Cardiology referral

Continued

Table 2 Continued

Signs and symptoms	Diagnosis	Prognosis/management
<ul style="list-style-type: none"> Palpitations Dyspnoea 	Arrhythmia	ECG (\pm prolonged ECG monitoring such as Holter Monitor) \pm cardiology referral
<ul style="list-style-type: none"> Syncopal episodes (especially on exercise) \pm abnormal cardiac examination findings \pm family history of hereditary heart disease 	HOCM/aortic stenosis/long QT, etc	ECG reviewing QTc and PR intervals, delta waves, T wave changes Cardiology referral
<ul style="list-style-type: none"> Central crushing chest pain \pm radiating to jaw and arm Associated sweating, nausea and pallor 	Myocardial ischaemia	ECG for signs of ischaemia Cardiology referral
<i>Miscellaneous</i>		
<ul style="list-style-type: none"> Acutely painful vesicular rash Pain may precede rash 	Herpes zoster (shingles)	Analgesia

HOCM, hypertrophic obstructive cardiomyopathy; MI, myocardial infarction; NSAIDS, non-steroidal anti-inflammatory drugs.

PHYSICAL EXAMINATION

A thorough physical examination will often elicit signs that can help make a definitive diagnosis.⁸ It is important to include the following:

- ▶ A full set of vital signs, including blood pressure and oxygen saturations.
- ▶ Assessment of general appearance, including colour, level of alertness, breathlessness and evidence of anxiety/distress.
- ▶ Evaluation of pulse volume, rate and character.
- ▶ Range of motion studies of the arms to elucidate any relationship to pain.
- ▶ Inspection of chest for signs of trauma, bruising, asymmetry and localised swelling.
- ▶ Palpation of chest for tenderness (particularly at the location of described pain), crepitus, heaves or thrills. Hooking manoeuvre; hook fingers under lower costal margin and pull anteriorly—reproduces pain in slipping rib syndrome.
- ▶ Auscultation of lung fields for air entry, wheeze, crackles and pleural rub.
- ▶ Auscultation of precordium for heart sounds, murmurs and pericardial rub.
- ▶ Examination of abdomen for signs of tenderness (particularly epigastric), trauma and organomegaly.

FURTHER INVESTIGATION AND INTERVENTION

Acknowledging parental/patient anxiety and providing appropriate reassurance is usually all that is needed. Further investigations and interventions are reserved for those cases where the history and examination do not suggest a diagnosis or concerning features have been identified. Table 3 summarises the principal indications for further investigation/intervention.

FOLLOW-UP

Follow-up arrangements are determined primarily by the final diagnosis. Following initial review, many patients with a benign condition can be discharged and

reassured regarding the likely diagnosis and its natural history. However, in some patients, chest pain can become recurrent and severe, interfering significantly

Table 3 Chest pain—indications for further action

Investigation/intervention	Indication
CXR	Acute onset of severe pain Pain awakening from sleep History of drooling, foreign body ingestion Cough Fever Dyspnoea History/signs of significant trauma Abnormal pulmonary/cardiac auscultation
Trial anti-reflux medication/pH/impedance monitoring	Gastrointestinal-type pain (see text) Epigastric tenderness
ECG Further resources on interpretation of the paediatric ECG are available elsewhere ^{17 18}	Cardiac-type chest pain (see text) Cardiac red flags (see box 1) Pericarditic pain (see text) Any abnormal chest sensation/pain in a preschool child Palpitations Abnormal cardiac auscultation or diminished pulses Abnormal heart rate or rhythm Family history of sudden death, inherited arrhythmias, cardiomyopathy or ICD/pacemaker insertion
Referral to paediatric cardiology	Cardiac-type chest pain (particularly exertional) Abnormal ECG Potentially inherited cardiac disease Abnormal cardiovascular examination Exercise-induced syncope or dizziness Palpitations or cyanosis

CXR, chest radiograph; ICD, implantable cardioverter defibrillators.

Test your knowledge (answers to the quiz are after the references)

- Which of the following is true of chest pain in children?
 - It is more common in adolescents than younger children
 - Women are more affected than men
 - Idiopathic chest pain may account for up to half of all presentations
 - The main aim of follow-up is to detect for developing signs of serious pathology
 - Idiopathic chest pain can have a serious impact on quality of life
- Which of the following is the approximate percentage of paediatric chest pain that is cardiac in origin?
 - 80%
 - 50%
 - 20%
 - 1%
 - <0.01%
- Which of the following factors increases the likelihood that chest pain is cardiac in origin?
 - Family history of acute MI at 50 years of age
 - Past history of repaired Tetralogy of Fallot
 - Syncopal episode while swimming
 - Past medical history of asthma
 - 'Crushing' chest pain exacerbated by exercise
- Which of the following are true of idiopathic chest pain?
 - If this diagnosis is suspected, then no investigations are necessary
 - Following thorough assessment and arrival at this diagnosis, patients can safely be discharged without follow-up
 - It has a low mortality
 - It has a low morbidity
 - Is a source of considerable anxiety to parents/children
- Which of the following diagnoses fits best with these case scenarios?
 - Pneumothorax
 - Pericarditis
 - Tietze's syndrome
 - Gastro-oesophageal reflux
 - Hyperventilation syndrome
 - Precordial catch
 - Asthma
 - Costochondritis
 - 12-years-old presenting with recurrent retro-sternal tightness and dyspnoea when playing football. No syncope/acute symptoms at presentation.
 - 15-years-old presenting with localised pain over the fifth costochondral junction with some swelling
 - 4-years-old with chest pain, fever and tachycardia preceded by an exanthematous illness
 - 10-years-old complaining of short-lived, sharp pain over the left side of the chest with no precipitating/relieving factors. Normal examination.
 - 14-years-old boy who is 1.85 m tall and weighs 62 kg presenting with acute right-sided chest pain and dyspnoea.

with activities of daily life. A follow-up study of 149 children presenting with chest pain showed that 43% still experienced chest pain at 6 months. Although the diagnosis was often altered over this time period, the commonest change was to a diagnosis of idiopathic chest pain and no serious organic disease was picked up after the initial assessment.⁸ Likewise, the Harvard study of 3700 patients over 10 years recorded no cardiac deaths in patients discharged from their clinic.⁴ These two studies provide further evidence that appropriate initial assessment of chest pain is all that is needed to reassure and discharge the majority of patients.

In certain circumstances, particularly in cases of diagnostic uncertainty, it is pertinent to arrange

provisional follow-up that can be cancelled should symptoms resolve. In the majority of these cases, follow-up will be important primarily to manage the patient/parents' ongoing anxiety surrounding the chest pain rather than monitoring for new signs of serious pathology.
