Long-term follow-up of survivors of childhood cancer (SIGN Clinical Guideline 132)

Hoong-Wei Gan,1,2 Helen A Spoudeas2,3

BACKGROUND

Five-year childhood cancer survival rates have increased to 80–90% for some tumours due to intensified treatments and better supportive care imposed on an incidence stable over four decades.1 2 Between 2005 and 2012, the number of UK survivors has risen from 26 000 to 33 000, or from 1:1000 to 1:715 UK adults.3 4 However, 40% experience chronic severe or life-threatening consequences (‘late effects’) of their tumour and/or its treatment.5 The recent National Cancer Survivorship Initiative (NCSI) has highlighted the unmet need in service provision for adult childhood cancer survivors, with a proposed survivorship framework and stratified care pathways modelled on >20 years’ prior experience.6 7

In March 2013, the Scottish Intercollegiate Guidelines Network (SIGN) published updated guidance on long-term follow-up of childhood cancer survivors to aid the ‘identification, assessment and management of late effects’ aimed at primary, secondary and tertiary healthcare practitioners.8 The Guideline Development Group (GDG) included representatives from paediatric haematology, oncology, endocrinology, reproductive medicine, cardiology, general paediatrics and general practice, as well as a survivor.

PREVIOUS AND OTHER ASSOCIATED GUIDELINES

The previous SIGN 76 guideline was published in 2004. This revision updates information on fertility preservation, cardiac late effects and patient information provision, and provides new sections on subsequent primary cancers (SPCs), bone health and metabolic syndrome. The UK Children’s Cancer Study Group’s (UK CCSG) best practice statement3 is a potentially valuable companion guideline for tertiary care practitioners requiring details of therapeutic regimens and their toxicity profiles to individualise care for those most affected.

KEY ISSUES

▸ Section 11: long-term follow-up provides a useful summary of the recommendations. It recognises the multisystemic and evolving nature of late effects over decades of survival, concluding a need for lifelong multidisciplinary follow-up (table 1). The authors suggest a three-tiered follow-up stratified by disease-related and/or treatment-related morbidity risk (table 2) and list the key multidisciplinary professionals required (box 1).

▸ Subsequent primary cancers (SPCs)—The British Childhood Cancer Survivor Study10 and others have shown an excess SPC risk—>50% due to gastrointestinal, genitourinary, breast and lung cancers—persisting into old age.

▸ Fertility—The impact of cancer treatment on the pituitary–gonadal axis, reproductive capacity and options for pretreatment fertility preservation are complex and differ between the sexes (see British Fertility Society review for a fuller discussion11). In boys, post-treatment sub/infertility may exist despite a normal puberty and potency.12 With intracytoplasmic sperm injection, oligospermia is no barrier to fertility preservation, while long-term spermatogenic recovery is possible.13 By contrast, pubertal delay or secondary amenorrhoea may herald sub/infertility in girls whose options are more limited. Pretreatment gonadotropin-releasing hormone analogues, ovarian transposition and oocyte collection are unproven and/or impracticable. Prepubertal children of either sex have no recommended options outside a clinical trial. Miscarriage rates are increased, but

there is no excess of congenital or genetic disorders in offspring.

**Cardiac effects**—Anthracycline-induced heart failure and mediastinal irradiation-induced cardiovascular disease may take years to manifest and may be additive. There is limited evidence for prophylactic ACE inhibitors or β-blockers, hence standard heart failure management is recommended.

**Bone health**—Bone mineral density (BMD) as measured by DEXA is age-dependent, sex-dependent, puberty-dependent and height-dependent, thus Z-scores rather than T-scores need cautious interpretation. The only evidence-based treatment for osteopenia is sex steroid replacement, although its effect on fracture risk is unknown.

**Metabolic syndrome**—Studies are limited to acute lymphoblastic leukaemia (ALL) and brain tumour survivors. A normal body mass index (BMI) does not preclude insulin resistance and dyslipidaemia. Annual blood pressure and BMI assessments are recommended.

**Cognitive/psychosocial issues**—Cranial irradiation-induced cognitive decline is age-dependent, sex-dependent, puberty-dependent and compounded by adjuvant chemotherapy and cognitive development. All survivors are at increased risk of psychiatric morbidity. Support networks and the importance of long-term follow-up should be given to all survivors.

**Growth**—All new cancer patients require accurate auxology at diagnosis and regularly thereafter to adult height, although the feasibility of performing this means that low-risk patients will need monitoring in primary or secondary care. Growth hormone (GH) replacement—important for bone mineralisation and childhood growth—does not increase cancer recurrence and should be substituted early particularly after spinal irradiation as it cannot fully reverse the detriment on adult height.

**Thyroid dysfunction**—Low-dose irradiation scatter can cause compensated and frank primary hypothyroidism years after treatment. Secondary hypothyroidism occurs if reduced height velocity.

Thyroid function tests: At end of treatment and then annually. Thyroid hormone replacement is recommended.

**Information provision**—Information on healthy lifestyle, support networks and the importance of long-term follow-up should be given to all survivors. Health and Care Excellence (NICE) SIGN does not require a mandatory cost-effectiveness analysis. Unlike the National Institute for Health and Care Excellence (NICE), SIGN does not require a mandatory cost-effectiveness analysis. INFORM—Information on healthy lifestyle, support networks and the importance of long-term follow-up should be given to all survivors. Health and Care Excellence (NICE) SIGN does not require a mandatory cost-effectiveness analysis. In our experience, the only evidence-based treatment for osteopenia is sex steroid replacement, although its effect on fracture risk is unknown.

Metabolic syndrome—Studies are limited to acute lymphoblastic leukaemia (ALL) and brain tumour survivors. A normal body mass index (BMI) does not preclude insulin resistance and dyslipidaemia. Annual blood pressure and BMI assessments are recommended.

**Guideline review**—SIGN guidelines represent a synthesis of systematic reviews summarising the best available evidence in accordance with standardised methodology. Unlike the National Institute for Health and Care Excellence (NICE), SIGN does not require a mandatory cost-effectiveness analysis. INFORM—Information on healthy lifestyle, support networks and the importance of long-term follow-up should be given to all survivors. Health and Care Excellence (NICE) SIGN does not require a mandatory cost-effectiveness analysis. In our experience, the only evidence-based treatment for osteopenia is sex steroid replacement, although its effect on fracture risk is unknown.

SIGN, Scottish Intercollegiate Guidelines Network.

The hierarchy of evidence from level 1 (meta-analyses, systematic reviews or randomised controlled trials) to level 4 (expert opinion).

HOW DO I IMPLEMENT THESE GUIDELINES IN MY PRACTICE?

- **Primary care practitioners** need to be alert to the many late organ toxicities incurred by increasing treatment intensity that may manifest decades after treatment. Lifelong surveillance for endocrinopathies, subfertility,

  SPCs, cardiovascular disease, obesity and metabolic syndrome particularly in low-risk patients can only realistically occur in primary care, alongside supporting healthy lifestyle behaviours (including monitoring vitamin D status) and participation in secondary/tertiary follow-up. Young adult survivors may seek support for psychological illness or subfertility.

- **Secondary care practitioners** will monitor growth, puberty, thyroid function and neurocognitive development until adulthood, with appropriate specialist referral. Letters of support may be required for missed school attendances, statementing and disability living allowance applications. Adult physicians will be responsible for lifelong monitoring of cardiovascular disease, obesity, thyroid function, bone and sexual health, fertility and SPCs.

- **Tertiary care practitioners** should see all those at highest risk (brain, pelvic, bone tumour and transplant survivors) for hypothalamic-pituitary hormone dysfunction, fertility counselling, cardiac and cognitive assessments and psychological support. Clear end-of-treatment summaries with information regarding long-term surveillance needs and likely consequences are required. Implicit in the latter are the increased resources needed for such age-appropriate tertiary assessment and rehabilitation services.

CONTROVERSIES AND UNADDRESSED ISSUES

The level of care provided to childhood cancer survivors remains highly variable across the UK,¹⁹ and controlled trials on the optimum frequency, duration and...
quality of follow-up are still needed to determine the effectiveness of secondary prevention of, for example, congestive cardiac failure or hypocortisolaemic (Addisonian) crises. A pan-European prospective cohort study of ~80 000 childhood cancer survivors (PanCareSurFlup) is currently examining risk factors for cardiac disease, SPCs and late mortality. Several issues not discussed in the guideline are summarised in box 2.

**Box 2 Critical review**

- Timely update limited by absence of high-quality evidence for the cost effectiveness of the recommended lifelong three-tiered follow-up framework. Evidence graded mainly C–D (none above B) consisting largely of uncontrolled qualitative studies of patient/family satisfaction, not morbidity or mortality.
- Inherent bias in Guideline Development Group (GDG) composition—no renal, respiratory or neurology/neuropsychology representatives with consequent omissions of important treatment-related renal, neurological and pulmonary toxicities (detailed in the UK CCG Best Practice Statement).
- The Human Fertilisation and Embryology Act (2008)22 governing storage and use of haploid gametes and embryos is not mentioned. It mandates personal (not proxy) consent, even in children; hence an intellectual (‘Gillick’) competency assessment is required. Blood-borne virus (HIV, hepatitis B & C) testing prior to storage and written consent regarding use after death is also necessary.
- The endocrine and cognitive outcomes sections have not been updated (cited references are over 15 years old). As a result:
  - The cited data on pituitary craniopharyngiomas and hypothalamic obesity have been superseded by prospective outcome studies,23 retrospective reviews24 and guidelines,25 not identified by the GDG search strategy.
  - The recommendation that all cranially irradiated patients receive annual cognitive assessments has never been achieved even in the context of a prospective trial.15
  - The perception that cranial irradiation per se causes eventual life-threatening pituitary deficits (eg, adrenocorticotrophic hormone deficiency deficiency) persists from 1987 data on adult pituitary tumours; newer evidence suggests pituitary dysfunction is confined to GH deficiency and precocious puberty except in the presence of a suprasellar tumour, which is most likely causative.26
  - Given the risk of radiation-associated subsequent primary cancers (1% lifetime risk of thyroid cancer), the carcinogenicity of nuclear fallouts and an elevated thyroid-stimulating hormone (TSH)27 and the long-term cardiovascular mortality risk of subclinical hypothyroidism,28 few clinicians would overlook screening for and treating compensated hypothyroidism (raised TSH, normal free T₄) after neck irradiation.
